**Background**: Mexico is a developing country with one of the highest youth obesity rates worldwide; > 34% of children and adolescents between 5 and 19 years of age are overweight or obese.

**Objectives**: The current review seeks to compile, describe, and analyze dietary conditions, physical activity, socioeconomic status, and cultural factors that create and exacerbate an obesogenic environment among Mexican youth.

**Design**: A narrative review was performed using PubMed and the Cochrane Library databases, as well as grey literature data from the Mexican government, academics, and statistical reports from nongovernmental organizations, included in electronic formats.

**Results**: The recent socioeconomic and nutritional transition has resulted in reduced healthy meal options at public schools, high rates of sedentary lifestyles among adolescents, lack of open spaces and playgrounds, socioeconomic deprivation, false or misunderstood sociocultural traditional beliefs, misconceptions about health, a high percentage of overweight or obese adults, and low rates of maternal breastfeeding. Some of the factors identified are exacerbating the obesity problem in this population. Current evidence also shows that more policies and health programs are needed for prevention of childhood and adolescent obesity. Mexico presents alarming obesity levels, which need to be curtailed and urgently reversed.

**Conclusions**: The present narrative review presents an overview of dietary, physical activity, societal and cultural preconceptions that are potentially modifiable obesity-promoting factors in Mexican youth. Measures to control these factors need to be implemented in all similar developing countries by governments, policy makers, stakeholders, and health care professionals to tackle obesity in children and young people.

**Keywords**: health determinants; developing countries; childhood obesity; health and environmental change

**Introduction**

According to the World Health Organization (WHO), obesity is defined as the fatness level sufficient to increase risk of morbidity or mortality (1). The prevalence of this health issue in young populations has risen substantially worldwide in less than one generation, especially in developing countries (2).

Excess body fat in children and adolescents can lead to a variety of clinical conditions and psychosocial disorders such as nonalcoholic fatty liver disease, sleep apnea, type 2 diabetes, asthma, cardiovascular disease, hypercholesterolemia, glucose intolerance and insulin resistance, skin conditions, menstrual abnormalities, impaired balance, orthopedic problems, and poor learning skills, which can lead to social discrimination. All of these conditions contribute to an increased morbidity and/or premature mortality (2–6). The worldwide prevalence of overweight and obesity in children under 5 years of age increased from 4.2% in 1990 to 6.7% in 2010. This trend is expected to continue rising to reach an estimated prevalence of 9.1% in 2020 (7). In low-to-middle-income countries of Latin America there have been rising rates of overweight...
and obesity over the past three decades, which have not spared children and adolescents (7, 8). It is estimated that one of every four or five children and adolescents in Latin America is overweight or obese, which represents 20–25% of the overall youth population in this region (9, 10).

Mexico is one of the developing Latin American countries and is the 11th most populated in the world (11). Almost half of the population is classified as poor or vulnerable to social deprivation (12, 13). As with many countries with similar characteristics, during the last 30 years Mexico has suffered from several demographic, economic, environmental, and cultural changes that have had an adverse impact on its citizens’ lifestyle and wellbeing. Approximately 75% of all deaths in Mexico are caused by noncommunicable diseases (14). Obesity and unhealthy diets are among the main risk factors of mortality (14, 15), and obesity-related comorbidities end the lives of 28% of Mexicans per year, a total of 170,000 people (16).

Obesity rates in Mexico have reached near-epidemic proportions, and generalized obesity appeared before the earlier historic malnutrition problem was solved. Therefore, both conditions currently coexist (13, 17). These two nutritional problems within the same population represent a high risk of obesity for the most vulnerable sectors – adults living in poverty and their offspring (13, 17–20).

Childhood obesity is a problem that is increasing rapidly in Mexico (21). According to obesity prevalence estimates, using WHO reference data, for children younger than 5 years of age Chile has the highest prevalence of obesity at 10.3% (2012) (22), followed by 9.8% in Mexico (2012), 6.9% in Peru (2007–2010), and 5.2% in Colombia (2010). For school-aged children, Mexico tops the list at 11.8% for girls and 17.4% for boys (2012), followed by 14.3% in Brazil (2009) and 5.2% in Colombia (2010). In adolescent populations, the data suggest that Mexico has the highest rates, with 12.1% for girls and 14.5% for boys (2012) followed by 7.3% in Brazil (2009) and 3.4% in Colombia (2010) (10).

Once established, obesity is difficult to treat, and the excess body weight in youth increases the risk of presenting obesity in adulthood; with the concomitant increased risk of early-onset obesity and the related noncommunicable diseases (23–25).

Childhood obesity is the result of complex and interacting dynamics that create an obesogenic environment, which includes biological, social, and behavioral factors acting within the influence of the youth’s family and community environment, in which the available options tend towards exacerbating the problem (3–6). However, although young Mexicans grow up in a more obesogenic environment than other cultures, not all these children and adolescents become obese. Thus, understanding obesity-promoting factors, how these factors interact with the youth environment, and how these interactions predispose some youngsters to becoming overweight or obese are important matters for future preventive approaches.

Scientific information is scarce regarding these factors in Mexican children and adolescents. Thus, the aim of the current narrative review is to compile, describe, and analyze dietary conditions, physical activity, socioeconomic status, and cultural factors that create and exacerbate an obesogenic environment among Mexican young people – factors that need to be considered for intervention, health programs, and policies in the near future.

**Methods**

**Obesity-promoting factors in Mexican youth populations**

PubMed and the Cochrane Library databases were searched for Spanish or English language manuscripts of obesity-promoting factors in Mexican children and adolescents, using a combination of the connectors ‘AND’ or ‘OR’. The keywords were ‘obesity’, ‘Mexico’, ‘children’,

Obesity-promoting factors in Mexican youth

Citation: Glob Health Action 2016, 9: 29625 - http://dx.doi.org/10.3402/gha.v9.29625

Results

Potential modifiable obesity-promoting factors in Mexican youth populations

The following obesity-promoting factors were identified in the youth populations of Mexico or other developing countries.

Dietetic

Mexico is suffering through a nutritional transition in which there has been a decline in traditional and homemade diets, contrasting with an increase in the consumption of commercial products, fast food, and food prepared away from home (27, 28). The average Mexican diet is based on high saturated fat, low protein, and low fiber intake (28). Between 1999 and 2006, an increase of 226% in the consumption of carbonated drinks and sweetened beverages was documented among Mexican children and adolescents (13). Mexican children have an overall daily water intake below the recommended levels, and the major liquid contributors to total energy intake are high-fat milk, fruit juices, and carbonated and noncarbonated sweetened soft drinks (29–31). Estimates indicate that plain water accounts for only 26.5% of their daily water intake (29). In the school environment, where children and adolescents spend most of their time, healthy food options are nonexistent, and low quality meals have been noted in full-day public schools. A lack of available potable water has coincided with the increased proliferation of calorically enhanced (sweetened) beverages in schools (29, 31). Moreover, a low level of knowledge regarding dietary components in school children has been identified (28).

Physical activity

The 2012 Health and Nutrition National Survey (Encuesta Nacional de Salud y Nutrición-ENSANUT 2012) showed that 58.6% of children between the ages of 10 and 14 reported doing no extracurricular physical activity, whereas 67% spent more than 2 h/day in front of a television screen, a computer screen, and/or a gaming console (26). In the last decades, a shift in activity patterns has been noted, including increased indoor entertainment and decreased outdoor activities (34).

Within the school environment, three salient factors are of note: only 1 h/week of physical education is mandatory in Mexican schools; 96% of the teachers in charge of physical education do not program their classes; and there is a lack of open spaces and playgrounds in schools and communities for performing physical activity (35–37). In addition, there is increasing pressure on children to perform academically, with reduced emphasis on sports (3). Physical activity and sedentary behavior are another part of the primary factors that influence energy balance and that have been used in childhood and adolescent treatments against obesity (33).

Other factors that promote sedentary behavior are the existence of a large number of insecure and unsafe neighborhoods, which discourages children from staying outdoors and playing with their friends (36). Time spent outdoors is one of the strongest correlates of physical activity among children, whereas the lack of security in playgrounds is one of the primary factors that parents

‘adolescents’, ‘obesogenic environment’, ‘obesity promoter factors’, and ‘developing countries’. The time restraints were publications between January 1990 and March 2015 so as to focus on the contemporary epidemiological and environmental circumstances of childhood and adolescent obesity. However, only a small number of publications related to Mexican youth populations with the above-mentioned characteristics were found. In some of the publications identified, the obesity-promoting factors in youth were not presented or were referenced to other studies or reports. Hence, we decided to widen the search to include grey literature data from the Mexican government, academics, and statistical reports from nongovernmental organizations (NGOs), including in electronic formats.

A systematic review was not feasible and a narrative review was performed instead. Further, apart from answering specific research questions, the principal aim of this work was to compile, describe, and analyze the obesity-promoting factors that can be identified in Mexican youth. From identified references, every obesity-promoting factor identified in this population, as well as those recognized in studies performed in other developing countries that have very similar population characteristics to Mexico, were collated and discussed. Four main categories were created to organize the information collected: 1) dietetic; 2) physical activity; 3) social, economic, and cultural conditions; and 4) genetic, hormonal, and behavioral alterations. The factors included in each of these categories were classified according to population characteristics: 1) factors identified in the Mexican population that promote obesity among youth; 2) factors in the Mexican population that could promote obesity among youth; and 3) factors identified in developing countries that could promote obesity among Mexican youth. Further, the types of studies included in this narrative review were identified.

Citation: Glob Health Action 2016, 9: 29625 - http://dx.doi.org/10.3402/gha.v9.29625
consider when selecting locations in which to allow their children free-time physical activity (38). Additionally, there are few open spaces and playgrounds in schools and communities, which results in reduced physical activity. Finally, beliefs that girls should not play sports, but should rather be mostly engaged in household chores, still prevail in Mexican society (3, 37).

Social, economic, and cultural conditions
Statistical analyses relating globalization to increasing obesity rates are difficult to quantify (39). Nevertheless, globalization may contribute to nutritional transition in developing countries by being simultaneously a product and a driver of technological change, thus providing similar causal links with overweight and obesity (3, 39).

In Mexico, noticeable socioeconomic deprivation has been described, involving high poverty levels where 45.5% of the population is classified as poor and 28.6% as vulnerable to social deprivation (12, 40, 41). Low household incomes, where the main income is about US $5/day for the average family of four members (40, 41), exacerbate the consequences of healthier diets being more expensive than other (cheaper) diets (42–46).

The nearly 2,000-mile border with the United States and friendly trade relations between the countries make it easier to pump junk food into Mexico. After the United States, Canada, and Mexico signed the North American Free Trade Agreement in 1994, processed food sales grew by 5–10% per year between 1995 and 2003 (22).

Since 1990, Mexico has experienced an important rural-to-urban migration (47). According to the National Statistics and Geography Institute (41), a rural area is defined as a region where fewer than 2,500 inhabitants live, whereas urban areas have more than 2,500 inhabitants. Nowadays, more than 76% of the population lives in urban areas, leaving less than 24% in rural regions (44). Rural-to-urban migration and rapid urban growth may contribute to the shift in the diet of rural migrants, who abandon diets that are typically rich in vegetables and cereals in favor of those high in processed meat and animal fat content. This change of diet is accompanied by reduced levels of physical activity, resulting in increased rates of overweight and obesity (48–50).

Traditional mistaken beliefs and misunderstandings about health and nutrition persist down the generations, where many mothers and grandmothers still believe that overweight or obese children have the appearance of health, leading to overprotection and overfeeding by parents or grandparents (22–36).

High exposure to TV advertising of food items has been identified as a contributing factor (45). On average, 61 TV commercials per day are transmitted, of which 42% are related to the consumption of food items that are conducive to obesity (37). Added to this, these products can be easily acquired outside schools, cinemas, theatres, and recreational sites. As such, obesity among youth is actively promoted by social factors of peer pressure that are exploited by advertising (37).

Genetic, hormonal, and behavioral alterations
Genetic and hormonal factors are also promoter agents within the population, but they are less predominant than lifestyles and habits (3).

It is important to note the observations of Lobstein et al. (51), who showed that Mexico's data follow a pattern where children's heights are consistently below the WHO reference values (by about 6 cm) and their weights are also lower than reference values (by about 1.4 kg). In addition, their body mass index (BMI) values are consistently higher than WHO reference standards (about 1.1 kg/m² above). Therefore, an apparent increase in the prevalence of overweight cannot be attributed entirely to excess bodyweight per se, but is a value that is confounded by a low height for age in these children (51).

Mexican children have also reported altered sleep patterns, which are also related to higher BMI in childhood and adolescence (52, 53). Furthermore, approximately 73% of Mexican adult females and 69.4% of Mexican adult males are overweight or obese (26), and as parents they play an important role in the quantity and quality of food consumed and the activity patterns of their children. This implies transference of eating and lifestyle patterns from parents to children (54, 55). Of the women of childbearing potential, 73% are overweight or obese, and only 14.4% of Mexican mothers breastfeed their children through the first 6 months of life (26). Maternal pregestational overweight or obesity is negatively associated with breastfeeding incidence and duration and positively associated with the child's weight (56, 57). The impact of pregestational overweight is a three-fold higher risk of childhood obesity, whereas excessive gestational weight gain is associated with a 33% offspring obesity (56, 57). Moreover, children who are breastfed have an approximate 24% less risk of presenting overweight or obesity (57).

Data on Mexican dietary constituents and physical activity practice patterns, together with social, economic, cultural, behavioral, hormonal, and genetic alterations that promote obesity among children and adolescents, are summarized in Table 2.

In the present narrative review, the studies included were observational, with five cross-sectional studies, one qualitative phenomenological study, and one qualitative-quantitative study pertaining to Mexican youth obesity—promoting factors. There were no longitudinal studies (Table 3).

Current strategies performed to reduce children and adolescent obesity in Mexico
The Mexican government and health institutions have implemented several strategies to prevent childhood and

adolescent obesity. Unfortunately, most of these actions have not been publicly evaluated as yet, nor have results indicating their effectiveness been published. To achieve the full potential of these interventions, particularly in low- and middle-income countries, evaluations need to be conducted to document the programs’ implementation, and the results should be widely disseminated (58).

One of the latest interventions by the Mexican government was the introduction of taxes on sugar-sweetened beverages of about 1 peso (US $0.06) per liter. Preliminary data published by the Public Health National Institute reports an average decline of 6% in purchases of these taxed beverages and an almost 4% increase in purchases of untaxed beverages in 2014, compared to pretax trends (59). In addition, the international 5-a-Day program has been implemented as a cooperative venture between private and public associations in Mexico. For a qualitative study published on the program, the general population was interviewed and the results showed that none of the persons interviewed considered the program to have a sufficient budget or marketing strategy (60). Moreover, the people interviewed felt that this program was not popular among the Mexican population, and that it lacked the support of the national authorities (60).

In 2015, the Mexican Institute for Competitiveness analyzed the implementation of ongoing federal policies for reducing obesity rates in the country (61). The NOURISHING framework, created by the World Cancer Research Fund for reporting and categorizing comprehensive food policies to promote healthy diets, was used (62). This framework is based on the understanding that food policies to prevent obesity should be aimed at improving dietary behavior by encouraging the availability, affordability, and acceptability of healthy diets (61, 62). The results of this analysis are shown in Table 4.

### Discussion

#### Challenges and opportunities

After considering all the obesity-promoting factors addressed in this manuscript, it is no surprise that the treatment and prevention of childhood and adolescent overweight and obesity remains a challenge in Mexico. It is clear that the average Mexican youth is surrounded by different factors that can lead to obesity. From a life-course perspective, the concern is that this health issue at this vulnerable period of life will have an impact on health not only at this stage but also in adulthood. Further, the general obesity problem in Mexico is not only a public health issue but also a public financial problem that affects families’ income, reduces the country’s competitiveness and productivity, and generates costs of up to 82% of the projected overall health expenditure (61, 63, 64). Consequently, the economic

and psychosocial costs of obesity, in combination with the associated comorbidities and sequelae, are outstanding and need to be addressed (58, 61, 62). Further, it is important to note that the majority of the obesity-promoting factors are potentially modifiable through interventions inducing behavioral changes. In the present narrative review, the seven studies included are observational and cross-sectional, but no longitudinal studies were included; hence we cannot evaluate the cumulative effects of chronicity.

From a national policy perspective, the NOURISHING framework opens new avenues that could help monitor the domains and areas that policy makers should cover within an appropriate policy design that helps fight obesity (62). Childhood and adolescence have been increasingly recognized as targetable by policies and interventions to reduce the obesity problem, since there are behavioral and obesity-promoting factors that can be changed at this life stage (55, 65). Additionally, a recent publication that analyzed food policies for the obesity problem concluded that policies should target the food preferences of the young, since comprehensive policy actions could create an enabling environment for youth to learn healthy food preferences and, as well, could target actions that empower disadvantaged populations to overcome barriers in order to acquire healthy preferences (66).

Nevertheless, interventions, health programs, and policies that encourage behavioral change need to include recognition of the influence of the wider social and economic environment (67). They should be adapted to each culture, so that possible barriers can be identified and overcome in order to produce effective health strategies to reduce youth obesity (51).

Multiple strategies that focus on healthy meals, sports, outdoor and home activities, family involvement, school activities, and community participation need to be encouraged (68, 69). Obesity prevention interventions should include the youngsters, parents, health care professionals, policy makers, schools, and the community in general, to ensure a significant effectiveness and impact on obesity prevalence and its long-term reduction (6, 58). Evaluating and disseminating the outcomes of such interventions is also important (6, 58).

Obesity is the result of increased energy intake or decreased energy expenditure, or a combination of both factors. From the results presented in this narrative review, some factors can play a major role in this energy imbalance, for example low water consumption and high consumption of carbonated drinks and sweetened beverages (29–31), in addition to cheap and readily available low-priced energy-dense foods (45). Also important to take into account is the phenomenon of overfeeding by parents (21), which can influence the physiologic mechanisms involved in obesity. These mechanisms have been focused on body-weight set-points based on a detection

Table 5. Recommendations to tackle obesity based on obesity-promoting factors identified in the literature
the leptin receptor (72), provides important elements of a molecular basis for this physiologic concept.

Based on obesity-promoting factors identified in this review, we can propose (Table 5) that childhood and youth obesity prevention in Mexico needs to be a joint effort between Mexican families, stakeholders, and policy makers. The table suggests some recommendations to tackle childhood and youth obesity in Mexican population based on the obesity-promoting factors identified in the literature. The recommendations are aimed at Mexican families and governmental policy makers and stakeholders. Priority recommendations are those combinations of factors identified in Mexican populations that promote obesity among youth. Two priority recommendations were identified for Mexican families: to encourage plain water consumption instead of carbonated and sweetened beverages in children; and to encourage physical activities and sports (indoor and outdoor) in children. Similarly, four priority recommendations were identified for the Mexican government, policy makers, and stakeholders: to focus the food industry, stakeholders, and governmental actions across sectors to ensure coherence in policies aimed at obesity prevention; to set fair prices for fresh fruits and vegetables; to provide the proper infrastructure to supply potable water at schools and public places; and to regulate high caloric content food advertising in cinemas, theaters, public places, and TV programming for children.

Conclusions
The present narrative review presents an overview of dietary, physical activity, societal and cultural preconceptions that are potentially modifiable obesity-promoting factors in Mexican youth. Measures to control these factors need to be implemented in all similar developing countries by governments, policy makers, stakeholders, and health care professionals to tackle obesity in children and young people.

Paper context
Mexico is a developing country with one of the highest youth obesity rates worldwide. Obesity is considered a severe health problem, especially in youth. Children and adolescents are a target population for policy making and interventions focused on tackling obesity. However, understanding Mexican youths’ obesogenic environment, obesity-promoting factors, their interactions, and how this could predispose children and adolescents to become overweight or obese is a key matter for future preventive approaches.

Authors’ contributions
MAM, EL, LT, RS, and MG all made substantial contributions to the conception or design, acquisition, analysis, and/or interpretation of data for the present work; each of the authors drafted the work or revised it critically for important intellectual content, and approved this version to be published. All of the authors agreed with all of the aspects presented in this work, ensuring that questions related to the accuracy or integrity of any part of the work were appropriately investigated and resolved.
