Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.
EPI-001, a compound active against castration-resistant prostate cancer, targets transactivation unit 5 of the androgen receptor

Castration-resistant prostate cancer is the lethal condition suffered by prostate cancer patients that become refractory to androgen deprivation therapy. EPI-001 is a recently identified compound active against this condition that modulates the activity of the androgen receptor, a nuclear receptor that is essential for disease progression. The mechanism by which this compound exerts its inhibitory activity is however not yet fully understood. Here we show, by using high resolution solution nuclear magnetic resonance spectroscopy, that EPI-001 selectively interacts with a partially folded region of the transactivation domain of the androgen receptor, known as transactivation unit 5, that is key for the ability of prostate cells to proliferate in the absence of androgens, a distinctive feature of castration-resistant prostate cancer. Our results can contribute to the development of more potent and less toxic novel androgen receptor antagonists for treating this disease.
INTRODUCTION

Prostate cancer (PC) is the second most common cancer in men and can be cured by surgery or radiotherapy in ca 70% of cases. The first line of pharmacological treatment for the remaining cases targets the androgen receptor (AR) because prostate cells depend on its activation by androgens for their growth and proliferation\(^1\). Activation can be prevented by combining androgen deprivation therapy, which inhibits the secretion of androgens by the testes, with the administration of antagonists that competitively bind to the binding site of androgens in the ligand-binding domain (LBD) of AR\(^2\).

Two to three years into this treatment PC patients inevitably develop castration-resistant prostate cancer (CRPC) as prostate cancer cells acquire the ability to activate AR at low levels of circulating androgens and in the presence of antagonists\(^3\). The mechanisms of aberrant activation are not well understood but appear to include the amplification of the AR gene and AR overexpression, the expression of constitutively active AR splice variants lacking the LBD, cell signaling cross-talk and mutations in both AR and transcriptional co-regulators\(^4\).

AR is a large multi-domain protein composed of globular ligand- and DNA-binding domains (LBD and DBD) and an N-terminal transactivation domain (NTD) that is intrinsically disordered (ID)\(^5,6\) (Fig. 1a). The function of the NTD (residues 1 to 558) is to recruit the basal transcription machinery by binding to general transcription factors either directly or assisted by transcriptional co-activators\(^1\). These protein-protein interactions are thought to cause the folding of binding motifs in a region of the NTD called activation function 1 (AF-1) that has not yet been characterized at high resolution (Fig. 1a,b)\(^6\). Inhibiting these interactions is considered a potential therapeutic approach for both PC and CRPC\(^7\), but the NTD has not been considered a suitable target for drug discovery due to its apparent lack of persistent secondary and tertiary structure.

The development of drugs that interact with ID regions has however recently been met with some success\(^8,9\), and has shown that targeting them with small molecules may be a viable therapeutic approach\(^10,11\). A particularly important development in this area was the recent discovery of EPI-001, an experimental drug for the treatment of CRPC identified by phenotypic screening that is efficacious both in cell lines and in an animal
model of this disease. In vivo EPI-001 binds irreversibly to the AR NTD and weakens its interaction with general transcription factors and transcriptional co-activators.

The discovery of EPI-001 represents an important milestone and a derivative of this compound is currently in clinical trials for CRPC (NCT02606123). The lack of a detailed understanding of the structural features of the domain and of the mechanism of action of this class of compounds represents, however, a hurdle for the rational design of optimized inhibitors. Here we reveal, by using solution nuclear magnetic resonance (NMR) spectroscopy, the structural properties of the ID regions of the NTD predicted to have a high propensity to fold and show that EPI-001 targets a region of sequence, known as transcription activation unit 5 (Tau-5), that is key for the ability of prostate cells to proliferate in the absence of androgens.

METHODS

Protein expression and purification The DNA sequences coding for human WT AR residues 265 to 340 (AF-1* 265-340), 330 to 448 (Tau-5*) and 142 to 448 (AF-1*) were cloned into Gateway pDEST17 vectors (Invitrogen) with an N-terminal His6-tag and a TEV cleavage site. Transformed E. coli Rosetta cells were grown at 37°C in LB medium for the production of non-isotopically labeled protein. For single (15N) or double (15N, 13C) isotopic labeling, cells were grown in minimal MOPS medium containing 15NH4Cl or 15NH4Cl and 13C-glucose, respectively. The AF-1* fusion protein accumulated in inclusion bodies which were solubilized in lysis buffer containing 8 M urea and fragmented by a pass through a cell disruptor at 25 kpsi. The fusion protein was purified by Ni2+ affinity chromatography in urea, which was removed by two dialysis steps, after which the His6-tag was cleaved by the TEV protease. The cleaved AF-1* was further purified by reverse Ni2+ affinity and size exclusion chromatography in 20 mM sodium phosphate buffer with 1 mM tris(2-carboxyethyl)phosphine hydrochloride (TCEP) at pH 7.4.

Peptides The synthesis of peptides R1, R2 and R3 (See SI) was performed by solid phase peptide synthesis by GenScript (peptide R1) or by ICTS NANBIOSIS, more specifically by the peptide synthesis unit of the CIBER in bioengineering, biomaterials & nanomedicine (CIBER-BBN) at the Barcelona science park (peptides R2 and R3). The
lyophilized peptides were dissolved in deionized water and the pH of the resulting solution was adjusted by addition of a concentrated NaOH solution. The concentration of these solutions was determined by amino acid analysis. The absence of intermolecular disulfide bonds in the R2 peptide, which contains one Cys residue, was confirmed by mass spectrometry (MS).

**Chemical synthesis of EPI-001 and stereoisomers** EPI-001 contains two stereogenic centers and can therefore be found as two pairs of enantiomers. We synthesized the four isomers with high diastereo- and enantioselectivity (Chiral HPLC). The synthesis followed the sequence detailed in Fig. S1 of the SI. Bisphenol A was treated with enantiomerically pure glycidol. The resulting diol was protected as dimethyl acetal and the free phenol was allowed to react with another isomer of glycidol. The corresponding diol was transformed into the epoxide and opened with CeCl₃. The treatment gave the final product by concomitant deprotection of the acetal. Full experimental details as well as the complete characterization of all isomers can be found in the SI.

**NMR** The assignment of AF-1* was obtained by using a *divide and conquer* approach. The resonances of fragments AF-1*₂₆₅-₃₄₀, Tau-5* (330 to 448) and AF-1* (142-448) were obtained by analyzing conventional three-dimensional triple resonance experiments acquired with standard Bruker pulse sequences on Bruker 600 MHz and 800 MHz spectrometers at 278 K in 20 mM sodium phosphate buffer with 1 mM TCEP at pH 7.4. The resonances of AF-1*₂₆₅-₃₄₀ and Tau-5* were equivalent to those of AF-1*, except for residues near the termini (Fig. S2), and allowed transferring the assignments from the former to the latter; the residues that were unique to AF-1* were assigned directly by analysis of the relevant spectra. To measure the perturbations caused by EPI-001, EPI-002, EPI-003, EPI-004 and EPI-005 (details available as SI) on the resonances of AF-1* appropriate volumes of a 50 mM stock solution of these compounds in 100% dioxane-d₈ were added to aliquots containing 25 µM AF-1*, 20 mM sodium phosphate, 1 mM TCEP, 10% D₂O, 30 µM DSS-d₆ at pH 7.4.

**RESULTS AND DISCUSSION**

As previously reported⁵,⁶,¹⁵ the sequence of the NTD has features typically encountered in ID regions¹⁶. It has a high content of Gly, Pro, polar and charged residues and, as
shown in figure 1b, possesses regions of low sequence complexity such as polyGln (residues 58-78, 84-89, 193-197), polyPro (372-379), polyAla (398-402) and polyGly (449-472) tracts. Such disordered tracts are commonly flanked by motifs of relatively low disorder propensity, with some helical propensity and rich in hydrophobic side chains, that are often involved in interactions with binding partners. An analysis of the sequence of the NTD with predictors of disorder and helical propensity indicates that several such motifs are indeed present in the domain and it has been proposed that they may correspond to the regions of sequence recognized by general transcription factors and transcriptional co-regulators (Fig. 1c,d,e).

A number of studies have aimed at identifying the regions of sequence of AF-1 that are essential for transcriptional activity. Two large regions of sequence, known as transcription activation units 1 and 5 (Tau-1, 102-371 and Tau-5, 361-537) have emerged as especially important (Fig. 1b). Tau-1 is crucial for the transcriptional activity of AR when the receptor is activated by androgens. Although Tau-5 is less well characterised, it has been shown to be more important than Tau-1 when activation occurs via androgen independent mechanisms in androgen depletion independent cell lines derived from CRPC patients and mouse xenograft models of PC. Efforts have also been directed at identifying the critical stretches of residues within these regions and suggest that for Tau-1 they correspond to residues 174 to 204 (core Tau-1) and for Tau-5 to residues 433 to 437 (WHTLF motif) (Fig. 1c).

**AF-1** is partially folded To investigate the structural properties of the NTD and its interaction with EPI-001 we cloned, expressed, purified and studied by NMR at 278K a 308-residue construct (AF-1*, residues 142-448) containing the part of AF-1 predicted to have a low disorder propensity (Fig. 1b and 1c), that is flanked by polyGln and polyGly tracts (Fig. 1b). In agreement with previous reports based on the use of other biophysical methods the \(^1\)H,\(^15\)N-HSQC spectrum of AF-1* had the features expected in an ID region such as low H\(^N\) chemical shift dispersion (Fig. 2a). In addition, and contrary to what is the case for NTD constructs containing residues 1 to 141, which include the polyQ tract (Fig. 1b), this region of the NTD was sufficiently stable to allow a characterization of its structural properties by solution NMR.
In spite of its ID nature, the AF-1 region of the NTD has been shown to have helical propensity by circular dichroism (CD) in buffer and in the presence of cosolvents that stabilize intramolecular hydrogen bonds, as well as in the presence of the natural osmolyte trimethylamine oxide (TMAO)\textsuperscript{5,22}. To identify the regions of sequence that adopt this secondary structure we assigned the resonances of AF-1* by a \textit{divide and conquer} approach (see Methods), compared the C\textalpha and C\textbeta chemical shifts, which are reliable reporters of secondary structure, to those predicted for disordered AF-1* (Fig. 2b)\textsuperscript{23} and used the SSP algorithm of Forman-Kay and co-workers\textsuperscript{24} to quantify the secondary structure propensity for the various residues of this construct from analysis of the backbone ($^{13}$C\textalpha, $^{13}$C\textbeta, $^{13}$CO, $^{15}$N, H\textit{N}) chemical shifts.

The results that we obtained indicated the presence of two regions of high helical propensity (defined as $\Delta \delta_{C\alpha}-\Delta \delta_{C\beta} > 1$ ppm and SSP \textless 0.5, corresponding to a helical propensity of 50%) which correspond to residues 185-200, in Tau-1, and 390-410, in Tau-5. Other regions of intermediate helical propensity (defined as $\Delta \delta_{C\alpha}-\Delta \delta_{C\beta} \approx 0.5$ ppm and SSP \textless 0.2) could be also identified, such as the region 230-240, in Tau-1, and 355-365 in Tau-5 (Fig. 2b, c). In addition to identifying regions of helical secondary structure the analysis of the chemical shifts also suggests that residues 144-154 and 270-290 of AF-1* adopt an extended conformation ($\Delta \delta_{C\alpha}-\Delta \delta_{C\beta} \approx -0.5$ ppm and SSP \approx -0.3) (Fig. 2b, c).

To further characterize the structural properties of AF-1* we characterized the dynamics of AF-1* by measuring the transverse relaxation rates ($R_2$) of the backbone $^{15}$N nuclei. Such relaxation rates are good reporters of nascent secondary structure and transient tertiary contacts in chemically denatured and ID proteins\textsuperscript{25}. The results that we obtained, presented in figure 2d, indicate that the regions with nascent secondary structure revealed by the analysis of the $^{13}$C chemical shifts (Fig. 2b) also display relatively high $R_2$ values. These are especially high, reaching values of ca 15 s\textsuperscript{-1}, for three regions of sequence found in Tau-5 predicted to have low disorder propensity\textsuperscript{26} and presenting, in two cases, high helical propensity.

Some of the regions of sequence that we identified as partially folded in AF-1* correspond in fact to the epitopes of binding partners of AR or are known to be important for the function of this receptor. In Tau-1, for example, the region that is most structured corresponds to \textit{core} Tau-1 (Fig. 2b). This region encompasses the motif
LSEASTMQLL\textsuperscript{192}, which is the binding epitope of TAB2, a component of the NCoR co-repressor complex\textsuperscript{27}. Partially folded residues 144 to 154, also in Tau-1, are part of the binding epitope of the amino-terminal bromodomains of BRD4\textsuperscript{28}. The region containing residues 230 to 240, of intermediate helicity, overlaps with the binding site of CHIP, a protein known to recruit the chaperone machinery by interaction with Hsc70, Hsp70 and Hsp90, which mediates the degradation of AR by the proteasome\textsuperscript{29} (Fig. 1e).

In Tau-5 the regions that we found to be partially folded are separated by motifs of low sequence complexity such as the Pro-rich region GPPPPPPPPP\textsuperscript{381} and the Gly-rich region GAGAAGPGSGPS\textsuperscript{426}. The former has been proposed to be the binding site of the SH3 domain of Src\textsuperscript{30} and the latter harbors a phosphosite, S424, which is thought to be important for transcriptional activity\textsuperscript{31}. Although we have not assigned the backbone resonances corresponding to the Pro residues in this Pro-rich motif, an analysis of the secondary chemical shifts of residues in its flanking regions (367-370, 385-388, Fig. 2b) suggests that it may adopt an extended conformation, likely of the polyproline II type, given the high Pro content; the polyproline II conformation is rather unusual but has been documented for several other IDPs.\textsuperscript{32} The chemical shifts and transverse $^{15}$N relaxation rates of the Gly-rich region (414-426, Fig. 2b,c,d) indicate, by contrast, that it is disordered, as expected due to its high Gly content.

No binding partners have yet been identified for regions 355-365 and 390-410, that are partially helical, but the WHTLF\textsuperscript{437} motif in region 433-447, corresponding to the core of Tau-5, has been proposed to bind both to activation function 2 (AF-2) in the LBD of androgen-bound AR\textsuperscript{33,34} and to histone acetyltransferase p300\textsuperscript{35}; in addition it has been shown to be indispensable for transcriptional activity in androgen depletion independent cell lines\textsuperscript{20}.

We noted that the helical propensity of the partially folded regions identified in both Tau-1 and Tau-5 (SSP \approx 0.5, corresponding to a population of helix of ca 50\%) is substantially higher than that predicted by algorithms that solely consider local interactions such as Agadir\textsuperscript{36} (Figs. 1e and 2b, c), indicating that non-local interactions may contribute to stabilizing the secondary structure. We thus investigated whether such non-local interactions included intramolecular contacts between residues in Tau-1 and Tau-5, similarly to what has been shown to occur in globular proteins under mild
denaturing conditions\textsuperscript{37}. For this analysis we used an NTD construct encompassing the part of Tau-5 contained in AF-1*, corresponding to residues 330-448 (termed Tau-5*, Fig. 1b). We compared the $^1$H and $^{15}$N chemical shifts of Tau-5* to those of AF-1* and observed that they were highly similar (Fig. S2). These results indicate that the chemical environment that residues in the Tau-5 region experience is the same both in the presence and absence of Tau-1. We conclude that the secondary structure present in AF-1* does not rely on long-range interactions between residues in Tau-1 and residues in Tau-5.

**EPI-001 interacts reversibly with Tau-5** It has been proposed that the mechanism of action of EPI-001 (Fig. 3a) involves two steps\textsuperscript{13}. The first step being the formation of a reversible complex between this compound and a specific conformation of AF-1 and the second the nucleophilic attack, by a protein side chain, on the C-Cl bond of EPI-001 to form an adduct unable to activate transcription. To investigate the first step of this mechanism and characterize the putative reversible complex we synthesized EPI-001 (details available as SI) and used NMR to analyze its effect on the resonances of AF-1* at 278 K. As shown by MS under these conditions the irreversible reaction of EPI-001 with AF-1* is sufficiently slow to allow the study of the reversible interaction by NMR (Fig. S5).

The results that we obtained, shown in figures 3b and c, indicate that EPI-001 causes small but highly reproducible changes in $^{15}$N chemical shifts in residues 354 to 448 of AF-1*, that correspond to Tau-5. Interaction with EPI-001 affects the resonances of a large number of residues, which are found in the three regions of sequence in Tau-5 identified as partially folded by the combined analysis of the backbone $^{13}$C chemical shifts and $^{15}$N transverse relaxation rates (Figs. 2b, 2d and 3b). We detected much smaller perturbations of the resonances of residues corresponding to Tau-1 even though this region contains partially helical regions such as residues in core Tau-1 (Figs. 2b and 3b). These results indicate that EPI-001 does not simply interact with any region of sequence with helical propensity but, rather, that this compound targets Tau-5 due to the ability of this sub-domain to adopt a conformation or, most likely, an ensemble of conformations that have affinity for it.
With the aim of further investigating the nature of the interaction we monitored the effect of AF-1* on the resonances of EPI-001. We observed that sub-stoichiometric amounts (25 µM and 50 µM) of AF-1* caused small but reproducible chemical shift changes in the $^1$H NMR spectrum of EPI-001 at 250 µM, as well as increases in linewidth similar to those commonly observed in small drug-like molecules transiently associating with macromolecules (Fig. S3). Together with our observation of perturbations in a large number of residues of AF-1* this result suggests that EPI-001 interacts with an ensemble of conformations adopted by AF-1* where these regions of sequence adopt a partially folded structure.

A large number of residues in Tau-5 experience chemical shift perturbations, more than what is expected for the binding of a small molecule. This can be due to the inspecific interaction of one or various molecules of EPI-001 with three independent interaction sites or to the combination of direct and indirect chemical shift changes due to structural changes occurring in Tau-5 upon interaction with EPI-001$^{38}$. To exclude that one or more EPI-001 molecules interact independently with the three regions of sequence of AF-1* where chemical shift perturbations are observed we monitored the effect on its $^1$H NMR spectrum of adding three peptides (R1 to R3) with sequences corresponding to regions 341-371, 391-414 and 426-446, respectively (details available as SI). We found that these peptides caused no changes in the spectrum of EPI-001, indicating that EPI-001 does not interact with them (Fig. S3) and confirming that residues 354-448 must simultaneously be present because they are necessary for binding this compound or for stabilizing the bound state of Tau-5* (Fig. 4).

It is interesting to note that Tau-5, the region of sequence of the NTD targeted by EPI-001, is partially folded, but it is important to emphasize that the data that we have obtained do not provide us with a mechanism of molecular recognition. It is possible that a conformational selection mechanism operates *i.e.* that EPI-001 interacts with a subset of the conformations that Tau-5* samples in equilibrium, but also that EPI-001 induces a new conformation in Tau-5*. Further work will be necessary to differentiate these two scenarios.
EPI-001 has two stereogenic centers and can therefore be found as four stereoisomers. To investigate whether the interaction between this compound and Tau-5 is stereospecific we synthesized the four stereoisomers (details available as SI) and studied their interaction with AF-1* by NMR. The results that we obtained (Fig. S4) indicate that the four compounds can interact with the NTD of AR, and thus the interaction appears to occur with little or no stereoselectivity. These results are in agreement with results obtained in vivo by Myung et al, who found that, although one of the stereoisomers tested was slightly more active than the other ones, the inhibitory activity of the four stereoisomers was similar.\(^{13}\)

Put together our results indicate that AF-1 is partially folded in regions of sequence that correspond to those which are functionally relevant for interacting with the transcription machinery and co-regulators of transcription. In addition, they reveal that Tau-1 and Tau-5, the two independent transcription activation units that are found in AF-1, correspond to different sub-domains that appear not to be involved in long-range interactions \textit{i.e.} are structurally and dynamically, at least under our conditions, independent. Finally, and most importantly, they show that Tau-5, that plays a particularly important role in AR activation in the absence of androgens, can be targeted by compounds such as EPI-001 (Fig. 4). Although the lack of stereoselectivity that we observe suggests that the binding mode of EPI-001 may not be sufficiently well-defined for conventional drug development our results are of relevance for drug discovery for CRPC because they suggests that the NTD, and Tau-5 in particular, may represent a suitable therapeutic target.

ACKNOWLEDGEMENTS

We thank J. M. Valverde (IRB) as well as the NMR facilities of the University of Barcelona (CCIT UB) and the Instituto de Química Física Rocasolano (IQFR, CSIC) for their assistance in, respectively, protein production and NMR.
